Multivariate Outliers w Mahalanobis Distance

2023-12-31

###IDENTIFYING MULTIVARIATE OUTLIERS USING MAHALANOBIS DISTANCE###

Identify what variables are in linear combination.

This could be, for example, a group of independent variables used in a multiple linear regression or a group of dependent variables used in a MANOVA.

Usually, this will include your predictor variable, any outcome variables, and any mediators or moderators.

Create a dataframe containing all of the variables you identified in step 1.

```
df <- data.frame(data$REACT, data$SUS, data$SOI, data$SMIRB)
head(df, 10)
## data.REACT data.SUS data.SOI data.SMIRB
## 1 5.375 1.066667 0.8888889 1.000000</pre>
```

```
## 2
           4.625 1.133333 2.4444444
                                       1.857143
## 3
           4.625 1.066667 1.8888889
                                      2.428571
                                      1.000000
## 4
           5.125 1.533333 1.7777778
## 5
           5.500 1.666667 1.5555556
                                       4.142857
## 6
           3.750 1.400000 1.1111111
                                       1.000000
## 7
           1.750 1.400000 1.0000000
                                      1.285714
## 8
           5.125 1.600000 2.1111111
                                       2.000000
           6.375 2.400000 3.4444444
## 9
                                       2.428571
## 10
           4.875 3.133333 4.5555556
                                       3.000000
###STEP 3###
```

Use the mahalanobis() function in R to calculate the distance for each observation:

```
df$mah <- mahalanobis(df, colMeans(df), cov(df))</pre>
head(df, 10)
##
      data.REACT data.SUS data.SOI data.SMIRB
                                                      mah
## 1
                                     1.000000 2.4467709
          5.375 1.066667 0.8888889
           4.625 1.133333 2.4444444
                                     1.857143 1.1614183
## 3
          4.625 1.066667 1.8888889
                                     2.428571
                                                2.0668241
## 4
          5.125 1.533333 1.7777778
                                    1.000000 1.5541001
## 5
          5.500 1.666667 1.5555556
                                    4.142857 8.5213431
                                     1.000000 2.9889809
## 6
          3.750 1.400000 1.1111111
## 7
          1.750 1.400000 1.0000000
                                     1.285714 11.0081866
## 8
          5.125 1.600000 2.1111111
                                     2.000000 0.1157724
## 9
          6.375 2.400000 3.4444444
                                     2.428571 5.6029036
## 10
          4.875 3.133333 4.5555556
                                     3.000000 10.9619960
###STEP 4###
```

Calculate p-values for each distance using chi-square

```
df$pvalue <- pchisq(df$mah, df=3, lower.tail = FALSE)</pre>
head(df, 10)
##
      data.REACT data.SUS data.SOI data.SMIRB
                                                              pvalue
## 1
          5.375 1.066667 0.8888889
                                     1.000000 2.4467709 0.48498762
## 2
          4.625 1.133333 2.4444444
                                     1.857143
                                               1.1614183 0.76227187
## 3
          4.625 1.066667 1.8888889
                                     2.428571 2.0668241 0.55865358
